## **Understanding Myeloma**

A guide for people with cancer, their families and friends

First published 1998. This edition September 2020.

© Cancer Council NSW 2020. ISBN 978 1 925651 96 6

*Understanding Myeloma* is reviewed approximately every two years. Check the publication date above to ensure this copy is up to date.

Editor: Rosemary McDonald. Designer: Eleonora Pelosi. Printer: SOS Print + Media Group.

### **Acknowledgements**

We thank the reviewers of this booklet: Prof John Gibson, Haematologist, Institute of Haematology, Royal Prince Alfred Hospital and The University of Sydney, NSW; Dr Stephanie Anderson, Registrar, Institute of Haematology, Royal Prince Alfred Hospital, NSW; Tanya Carney, Consumer; Jacqui Keogh, NSW State Manager/Senior Myeloma Nurse NSW, Myeloma Australia; Dr Silvia Ling, Haematologist, Liverpool Hospital, NSW; Rachel McCann, Myeloma Support Nurse NSW, Myeloma Australia; John McMath, Consumer; Karen Robinson, 13 11 20 Consultant, Cancer Council NSW.

We also thank the health professionals, consumers and editorial teams who have worked on previous editions of this booklet.

### **Note to reader**

Always consult your doctor about matters that affect your health. This booklet is intended as a general introduction to the topic and should not be seen as a substitute for medical, legal or financial advice. You should obtain independent advice relevant to your specific situation from appropriate professionals, and you may wish to discuss issues raised in this book with them.

All care is taken to ensure that the information in this booklet is accurate at the time of publication. Please note that information on cancer, including the diagnosis, treatment and prevention of cancer, is constantly being updated and revised by medical professionals and the research community. Cancer Council NSW excludes all liability for any injury, loss or damage incurred by use of or reliance on the information provided in this booklet.

### **Cancer Council NSW**

Cancer Council is the leading cancer charity in NSW. It plays a unique and important role in the fight against cancer through undertaking high-quality research, advocating on cancer issues, providing information and services to the public and people with cancer, and raising funds for cancer programs. This booklet is funded through the generosity of the people of NSW. To make a donation to help beat cancer, visit [cancercouncil.com.au](http://cancercouncil.com.au) or phone 1300 780 113.

# About this booklet

This booklet has been prepared to help you understand more about the blood cancer known as myeloma. Many people feel shocked and upset when told they have myeloma. We hope this booklet will help you, your family and friends understand how myeloma is diagnosed and treated. We also include information about support services.

We cannot give advice about the best treatment for you. You need to discuss this with your doctors. However, this information may answer some of your questions and help you think about what to ask your treatment team (see page 58 for a question checklist).

This booklet does not need to be read from cover to cover – just read the parts that are useful to you. Some medical terms that may be unfamiliar are explained in the glossary (see page 59). You may also like to pass this booklet to family and friends for their information.

## How this booklet was developed

This information was developed with help from a range of health professionals and people affected by the blood cancer myeloma. It is based on clinical practice guidelines for myeloma.<sup>1</sup>

If you or your family have any questions, call Cancer Council **13 11 20**. We can send you more information and connect you with support services in your area. You can also visit our website at [cancercouncil.com.au](http://cancercouncil.com.au).

# What is blood cancer?

Cancer is a disease of the cells. Cells are the body's basic building blocks – they make up tissues and organs. The body constantly makes new cells to help us grow, replace worn-out tissue and heal injuries.

Normally, cells multiply and die in an orderly way, so that each new cell replaces one lost. Sometimes, however, cells become abnormal and keep growing. In solid cancers, such as breast cancer, the abnormal cells form a mass or lump called a tumour.

Myeloma, however, is a blood cancer. It begins in the bone marrow, the spongy part in the centre of the bone where blood cells are produced. In myeloma, a type of white blood cell called a plasma cell is affected. Normal plasma cells produce antibodies, called

## How myeloma starts

Bone marrow produces three main types of blood cells: red cells, white cells and platelets.

Plasma cells are a special type of white blood cell. Myeloma starts when plasma cells become abnormal and multiply, crowding the bone marrow. They usually also release an antibody (paraprotein) into the blood.

### Bone marrow

Blood cells are created and mature in the bone marrow, the spongy part in the centre of the bone.

immunoglobulins, that protect us from infection. When plasma cells become abnormal, they are known as myeloma cells. They can reduce the bone marrow's ability to produce normal levels of other blood cells, which affects the way the body works.

Usually, the myeloma cells produce an abnormal antibody called paraprotein or monoclonal protein. This enters the bloodstream, weakening the immune system and damaging the kidneys. As myeloma progresses, paraprotein builds up in the blood. Without treatment, the bone marrow produces more myeloma cells and fewer normal blood cells. Myeloma can then spread to other parts of the body that contain bone marrow, such as the spine, skull, shoulders, ribs and pelvis.

#### Normal bone marrow

In healthy bone marrow, white blood cells (including plasma cells), red blood cells and platelets are kept in balance.

#### Bone marrow with myeloma

The bone marrow becomes crowded with abnormal plasma cells, so there are fewer normal white blood cells, red blood cells and platelets.

Plasma cells are a special type of white blood cell

Other white blood cells

Red blood cells

Platelets

# The blood

Blood is pumped around your body to provide oxygen and nutrients to your tissues, and to remove waste products. It is made up of red blood cells, white blood cells and platelets, and each has a set function.

All three types of blood cells live for a limited time and need to be continually replaced. Most are made in the bone marrow, which is the spongy part in the centre of the bones.

The bone marrow contains stem cells. These are un specialised blood cells that develop into mature red or white blood cells or platelets. Once mature, the blood cells are usually released into the bloodstream to carry out their set functions.

# Key questions

## Q: What is myeloma?

**A:** Myeloma is a type of blood cancer. It develops from white blood cells in the bone marrow called plasma cells. As bone marrow is found throughout the body, myeloma can affect multiple areas at the same time, and the disease is often called multiple myeloma.

Myeloma begins when abnormal plasma cells, known as myeloma cells, start multiplying. Normal plasma cells make different types of antibodies to help the body fight infections. Abnormal plasma cells make an antibody known as paraprotein, M-protein or monoclonal protein. Paraprotein is found in the blood of most people who have myeloma (see page 13 for more information).

Because the myeloma cells crowd out the bone marrow, there is less space for normal blood cells to develop and keep you healthy. As a result, a lack of:

- normal plasma cells and other white blood cells can make a person more likely to get infections
- red blood cells (anaemia) can cause fatigue
- platelets can cause bleeding and bruising.

## Q: How is it different from leukaemia?

**A:** Myeloma and leukaemia are both types of blood cancer, but they affect the body in different ways. Leukaemia is the name given to cancers of white blood cells, which are usually easily detected on a blood test. Myeloma is a cancer of the plasma cells, which are found only in the bone marrow and not usually found in the blood.

Cancerous plasma cells sometimes form a single tumour in the bone or tissue, rather than spreading throughout the bone marrow. Known as solitary or multiple solitary plasmacytoma, this tumour is less common and makes up only about 5% of plasma cell cancers. Plasmacytoma is often treated with radiation therapy. Some people may go on to develop additional plasmacytomas or myeloma.

## Q: What are the symptoms?

**A:** Myeloma can cause a range of symptoms because of its effect on the bones, bone marrow, blood, urine and kidneys. The most common symptoms of myeloma include:

- bone pain or a broken bone that has not been caused by injury
- frequent infections or an infection that is hard to shake off
- tiredness, shortness of breath or a racing heart, caused by a low level of red blood cells (anaemia)
- kidney problems, caused by the excess amounts of paraprotein produced by the myeloma cells. The symptoms of kidney problems include frothy urine, passing too much or too little urine, nausea, weight loss or fluid retention
- feeling sick, drowsy or confused, because of too much calcium in the blood (hypercalcaemia)
- abnormal blood counts, because myeloma cells may stop the bone marrow from making enough normal blood cells.

Other conditions can also cause these symptoms, so not everyone with these changes will have myeloma. However, if you are concerned or the symptoms are ongoing, see your general practitioner (GP) for a check-up.

## Q: What are the risk factors?

**A:** The causes of myeloma are unknown. We know that plasma cells become cancerous when there are certain changes in their DNA. DNA is found in all cells. It carries instructions that control how cells work, however, we do not know what causes DNA to change.

While exposure to certain chemicals (e.g. dioxins used in industry), high levels of radiation (e.g. from working in a nuclear power plant) and viruses (such as HIV) have been linked to an increased risk of myeloma, no known cause can be found in the majority of people with myeloma.

People with monoclonal gammopathy of undetermined significance (MGUS) are more likely to develop myeloma (see page 20).

Myeloma is not considered to be hereditary (inherited) and it is rare for more than one person in a family to be affected by this disease, although this does happen occasionally.

## Q: How common is myeloma?

**A:** Myeloma is not a common disease. About 1900 people in Australia are diagnosed with the disease each year.<sup>2</sup> It accounts for 13% of blood cancers and around 1% of all cancers generally.<sup>3</sup> The disease is more often found in people over 60, which is partly explained by the ageing population. It is rare in people under 40 years of age. Myeloma is slightly more common in males than in females.

## Q: Which health professionals will I see?

**A:** Your GP will arrange the first tests to assess your symptoms. If these tests do not rule out cancer, you will usually be referred to a specialist, such as a haematologist. Occasionally in regional areas, people may see a medical oncologist instead. The specialist will arrange further tests.

### Health professionals you may see

<b>GP</b>	assists you with treatment decisions and works in partnership with your specialists in providing ongoing care
<b>haematologist*</b>	diagnoses and treats diseases of the bone marrow, blood and lymphatic system; prescribes chemotherapy and other drug therapies
<b>radiation oncologist*</b>	treats cancer by prescribing and overseeing a course of radiation therapy
<b>pathologist*</b>	examines cells and tissue samples to determine the type and extent of the myeloma
<b>cancer care coordinator</b>	coordinates your care, liaises with other members of the MDT and supports you and your family throughout treatment; care may also be coordinated by a clinical nurse consultant (CNC) or clinical nurse specialist (CNS)
<b>nurse</b>	administers drugs and provides care, information and support throughout treatment

If myeloma is diagnosed, the specialist will consider treatment options. These will be discussed with other health professionals at what is known as a multidisciplinary team (MDT) meeting. During and after treatment, you will see a range of health professionals who specialise in different aspects of your care.

<b>pain management team</b>	consists of pain specialists and nurses who work together to treat pain, particularly if it is difficult to control
<b>dietitian</b>	recommends an eating plan to follow during treatment and recovery
<b>social worker</b>	links you to support services and helps you with emotional, practical and financial issues
<b>physiotherapist</b>	helps with restoring movement and mobility, and preventing further injury
<b>occupational therapist</b>	assists in adapting your living and working environment to help you resume usual activities after treatment
<b>counsellor, psychologist</b>	help you understand and manage your emotional response to diagnosis and treatment

*\* Specialist doctor*

# Diagnosis

Myeloma is diagnosed when blood and urine tests find a paraprotein or free light chains, and bone marrow tests show an increased number of plasma cells. Blood tests, x-rays and other imaging scans are used to check for damage to bones and body organs, such as your kidneys, caused by myeloma. The test results help your doctor work out the type of myeloma you have and the best treatment for you.

## Blood tests

Several blood tests are used to diagnose myeloma.

**Serum analysis** – The main blood test is called serum protein electrophoresis. This measures the level of paraprotein in your blood. Another blood test called the serum free light chain assay may be used to check for a form of paraprotein known as free light chains (see the *Understanding paraprotein* box on the opposite page).

**Blood tests** – These check for too few red blood cells (anaemia), too much calcium in the blood (hypercalcaemia), and how well your kidneys are working.

Once myeloma has been diagnosed, further blood tests will help your doctor work out the stage of the disease (see page 17). Changes in the level of paraprotein or free light chains indicate changes in the activity of the myeloma. If you are diagnosed with myeloma, your paraprotein and/or serum free light chain levels will be monitored to see how well treatment is working and to check that the myeloma is stable during periods when you are not having treatment. Blood tests are important for assessing the effect of myeloma on your normal body function.

## Understanding paraprotein

Myeloma cells produce an antibody known as paraprotein. To make a diagnosis of myeloma, doctors will look for this paraprotein in the blood or urine. Once you have been diagnosed with myeloma, doctors will regularly check your paraprotein levels to monitor the disease.

### Intact paraprotein

Paraprotein is made up of smaller proteins that are usually linked together to form a pair of long chains (called heavy chains) and a pair of shorter chains (called light chains). Most people with myeloma release complete (intact) paraprotein made up of both heavy and light chains. Intact paraprotein can be detected in a blood test.

### Free light chains

About 1 in 5 people with myeloma do not produce intact paraprotein. They produce only the light chain parts. These light chain parts are known as free light chains when detected in a special blood test, and as the Bence Jones protein when found in a urine test. Some people produce both intact paraprotein and free light chains.

### Non-secretory myeloma

Fewer than 1 in 50 people with myeloma produce little or no paraprotein. This is known as non-secretory myeloma. It makes diagnosis and monitoring more difficult.

## Urine and specialised blood tests

A urine test may be used to check for the Bence Jones protein, which is the light chain part of paraprotein (see previous page). About one-third of people with myeloma make enough Bence Jones protein for it to be measurable in urine.

For this test, you may be asked to collect your urine in a container over a 24-hour period. If the Bence Jones protein shows up, you may have regular urine tests to monitor the myeloma and check how well treatment is working.

Your doctor may also suggest you have a specialised blood test called the serum free light chain assay as well as, or instead of, the urine test as the Bence Jones protein doesn't show up in a standard blood test.

## Bone marrow aspiration and trephine biopsy

These tests are used to examine cells from the bone marrow. You will usually have a local anaesthetic and a mild sedative.

For the bone marrow aspiration, a thin needle is used to remove a sample of fluid (aspirate) from the bone marrow – usually from the pelvic bone, but sometimes from the chest. A trephine biopsy, sometimes done with a second needle, removes a small piece of bone with the marrow inside.

The bone marrow samples are sent to a laboratory for examination under a microscope. A medical specialist, called a pathologist, will

check the number of plasma cells in the sample and look for any damage to the bone marrow caused by myeloma.

You may also have a bone marrow aspiration and trephine biopsy at the start and end of each course of treatment. By comparing samples, your doctor can see how well the treatment is working.

After a biopsy, you may feel a bit drowsy and have some bleeding and discomfort at the biopsy site.

## Cytogenetic and molecular tests

The bone marrow sample may be used for cytogenetic and molecular tests, which examine the structure and function of cells. Each cell in the body contains chromosomes, which are made up of genes. These genes control all activities of the cell.

There may be changes in the structure of the chromosomes within myeloma cells, such as a part missing or deleted. The most common chromosomal abnormalities found in myeloma include t(4;14), t(14;16), del(17p) and del(13q). The changes help classify myeloma as either high risk or standard risk.

Cytogenetic, fluorescence in situ hybridisation (FISH) or other specialised molecular tests can look for changes in the chromosomes. By identifying any changed or damaged chromosomes, genetic tests help the medical team plan the most effective treatment and predict how the myeloma might respond.

## Imaging scans

Your doctor will usually arrange for x-rays to check your bones, and may suggest other imaging scans, such as a CT or MRI.

### X-rays and CT scans

Bone x-rays, sometimes called a skeletal survey, are used to find bone damage caused by the myeloma cells. X-rays are usually taken of your head, spine, ribs, hips, legs and arms. Areas of bone damage, known as lytic lesions, show up on x-ray film as black shaded areas. In the past, skeletal surveys were performed using traditional x-rays, however now you will have the more accurate CT (computerised tomography) skeletal survey. For this scan, you lie flat on a table while the scanner takes detailed pictures of your body. The scan takes about 30 minutes.

### MRI scan

An MRI (magnetic resonance imaging) scan can find myeloma both inside and outside the bones. It uses magnetic waves to create detailed cross-sectional pictures of areas of the body. Let your doctor know if you have a pacemaker as the magnetic waves can interfere with it.

For an MRI, you will lie on an examination table inside a large metal tube that is open at both ends. The noisy, narrow machine makes some people feel anxious or claustrophobic. If you think you may become distressed, mention it beforehand to your medical team. You may be given a mild sedative to help you relax, or you might be able to have a family member or friend in the room with you for support. You will usually be offered headphones or earplugs, and you may be able to bring along your favourite music to play. The MRI scan may take between 30 and 90 minutes.

## Dye injection for CT or MRI

CT and MRI scans of organs sometimes involve the injection of a dye (contrast) into a vein, probably in your arm. This dye makes the pictures clearer. Before having scans, let the person doing the scan know that you are suspected of having myeloma, as this dye can damage the kidneys and may not be safe for you. Also let the medical team know if you have any allergies or have had a reaction to contrast during previous scans, are diabetic or are pregnant. Scans of bones usually do not need any contrast to be injected.

## Other scans

In particular cases, your doctor may arrange specialised scans, such as a PET–CT (positron emission tomography–computed tomography) or sestamibi scan. Both of these scans involve an injection of a small amount of radioactive substance, which shows up areas of healthy and abnormal tissue and may help detect myeloma outside of the bone marrow. Most people with myeloma do not need these scans.

## Staging myeloma

The test results allow the haematologist to work out how far the disease has progressed. This process is called staging, and the information will help your doctor assign a stage to the myeloma. This is an indication of how much the myeloma has affected your body and how it is likely to respond to treatment.

If you have difficulty understanding the stage of the myeloma, ask your doctor to explain it in simple terms.

The most commonly used staging system for myeloma is the Revised International Staging System (R-ISS).

The R-ISS divides myeloma into three stages. Stage 1 is the earliest stage and stage 3 is more advanced. The stages are based on the results of various blood tests that check:

- **levels of beta-2 microglobulin (B2M)** – a protein produced by myeloma cells that shows the extent of certain diseases
- **levels of albumin** – a protein produced by the liver that is a sign of overall health
- **levels of lactate dehydrogenase (LDH)** – an enzyme released into the blood when cells are damaged or destroyed
- **genetic information** – specific chromosomal abnormalities that identify people at risk of the disease progressing.

### R-ISS staging system of myeloma

<b>stage 1</b>	<ul style="list-style-type: none"><li>• serum B2M is less than 3.5 mg/L</li><li>• albumin level is 3.5 g/dL or greater</li><li>• LDH levels are normal</li><li>• cytogenetics are considered not high risk</li></ul>
<b>stage 2</b>	not stage 1 or 3
<b>stage 3</b>	<ul style="list-style-type: none"><li>• serum B2M is 5.5 mg/L or greater, and either LDH levels are high or cytogenetics are considered high risk</li></ul>

## Significant signs of myeloma

Doctors usually use the CRAB criteria of myeloma-defining events to help identify people with myeloma who need to start treatment (see next page). The SLiM criteria was added as part of the R-ISS and consists of a set of three specific signs known as biomarkers. When used together, the criteria are known as the SLiM–CRAB criteria.

### CRAB criteria: myeloma-defining events

<b>C</b>	calcium levels in the blood are raised
<b>R</b>	renal (kidney) damage
<b>A</b>	anaemia (low levels of red blood cells)
<b>B</b>	bone pain and damage (areas of damage known as lytic lesions and/or bone loss known as osteoporosis can weaken bones making them more likely to fracture)

### SLiM criteria: biomarkers of malignancy

<b>S</b>	60% or more abnormal plasma cells in the bone marrow (plasmacytosis)
<b>Li</b>	light chain ratio (a high level of free light chains in the blood)
<b>M</b>	MRI lesions (bone abnormalities found by MRI of 5 mm or more in size)

## When to start treatment

Test results will help your doctor work out when to start treatment.

Category	Test results	Need for treatment
<b>monoclonal gammopathy of undetermined significance (MGUS)</b>	<ul style="list-style-type: none"> <li>• low level of paraprotein in blood or urine (less than 30g/L)</li> <li>• low level of myeloma cells in the bone marrow (less than 10% clonal plasma cells)</li> <li>• no SLiM-CRAB features</li> </ul>	<ul style="list-style-type: none"> <li>• not cancer; needs active monitoring as it may progress to myeloma</li> <li>• one out of every 100 people diagnosed with MGUS develops myeloma each year</li> </ul>
<b>smouldering myeloma (asymptomatic myeloma)</b>	<ul style="list-style-type: none"> <li>• medium level of paraprotein in blood or urine (greater than 30g/L) and/or myeloma cells in the bone marrow (10–59% clonal plasma cells)</li> <li>• no SLiM-CRAB features</li> </ul>	<ul style="list-style-type: none"> <li>• usually doesn't need treatment straightaway</li> <li>• may progress to active myeloma, so it needs active monitoring (see page 25)</li> </ul>
<b>active myeloma (symptomatic myeloma)</b>	<ul style="list-style-type: none"> <li>• SLiM-CRAB features</li> <li>• one of the following: greater than 60% (clonal) plasma cells in the bone marrow; ratio of abnormal to normal light chains is less than 100; abnormal MRI with more than one (greater than 5 mm) focal lesion</li> </ul>	<ul style="list-style-type: none"> <li>• active myeloma requires treatment (see pages 25–34)</li> </ul>

## Prognosis

Prognosis means the expected outcome of a disease. It is not possible for any doctor to predict the exact course of the disease, but your medical team can predict how the myeloma will respond to treatment based on several factors:

- your test results
- the type of myeloma you have, and its stage and rate of growth
- your age, fitness and medical history.

You will also have tests throughout your treatment that show how well the treatment is working.

The outlook for people with myeloma is improving constantly. While treatment cannot cure myeloma, it can help control the disease (known as plateau phase or remission).

If the myeloma is under control, symptoms improve and people usually return to a state of good health that may last for months or a few years. For some people, the disease can be controlled for much longer periods. When the disease becomes active again (disease progression, also called relapse or recurrence), further treatment will be needed. See pages 51–52 for details.

Living with myeloma may make you feel anxious. It may help to talk to a myeloma support nurse, or contact the hospital social worker or psychologist for support. You can also speak to other people who have myeloma (see page 55).

## Key points about diagnosing myeloma

### What it is

Myeloma is a type of blood cancer that develops from plasma cells in the bone marrow.

### Main tests

The main tests to diagnose myeloma are:

- blood and urine tests to measure the level of paraprotein
- bone marrow tests to measure the amount of myeloma cells in the bone marrow.

These tests may also be done at the beginning and end of each course of treatment.

### Other tests

- You are likely to have a bone x-ray (usually a skeletal survey) to look for areas of bone damage (lytic lesions).
- If a clearer picture of the bones is needed, you may have an MRI or PET-CT scan.
- The tests allow your doctor to classify the myeloma. MGUS is not cancer but may progress to myeloma. Smouldering (asymptomatic) myeloma does not have symptoms. Both MGUS and smouldering myeloma need active monitoring. Active (symptomatic) myeloma requires treatment.
- The SLiM-CRAB criteria are two sets of signs that help doctors decide when myeloma has become active and requires treatment.

### Staging

This indicates how much the myeloma has affected your body and how likely it is to respond to the proposed treatment.

# Making treatment decisions

Sometimes it is difficult to decide on the type of treatment to have. You may feel that everything is happening too fast, or you might be anxious to get started. Check with your specialist how soon treatment should begin – often it won't affect the success of the treatment to wait a while. Ask them to explain the options and take as much time as you can before making a decision.

**Know your options** – Understanding the disease, the available treatments, possible side effects and any extra costs can help you weigh up the options and make a well-informed decision. Check if the specialist is part of a multidisciplinary team (see page 11) and if the treatment centre is the most appropriate one for you – you may be able to have treatment closer to home, or it might be worth travelling to a centre that specialises in a particular treatment.

**Record the details** – When your doctor first tells you that you have cancer, you may not remember everything you are told. Taking notes can help, or you might like to ask if you can record the discussion. It is a good idea to have a family member or friend go with you to appointments to join in the discussion, write notes or simply listen.

**Ask questions** – If you are confused or want to check anything, it is important to ask your specialist questions. Try to prepare a list before appointments (see page 58 for suggestions). If you have a lot of questions, you could talk to a cancer care coordinator or nurse.

**Consider a second opinion** – You may want to get a second opinion from another specialist to confirm or clarify your specialist's recommendations or reassure you that you have explored all of your

options. Specialists are used to people doing this. Your GP or specialist can refer you to another specialist and send your initial results to that person. You can get a second opinion even if you have started treatment or still want to be treated by your first doctor. You might decide you would prefer to be treated by the second specialist.

**It's your decision** – Adults have the right to accept or refuse any treatment that they are offered. For example, some people with advanced cancer choose treatment that has significant side effects even if it gives only a small benefit for a short period of time. Others decide to focus their treatment on quality of life. You may want to discuss your decision with the treatment team, GP, family and friends.

► See our *Cancer Care and Your Rights* booklet.

### Should I join a clinical trial?

Your doctor or nurse may suggest you take part in a clinical trial. Doctors run clinical trials to test new or modified treatments and ways of diagnosing disease to see if they are better than current methods. For example, if you join a randomised trial for a new treatment, you will be chosen at random to receive either the best existing treatment or the modified new treatment. Over the years, trials have improved treatments and led

to better outcomes for people diagnosed with cancer.

You may find it helpful to talk to your specialist, clinical trials nurse or GP, or to get a second opinion. If you decide to take part in a clinical trial, you can withdraw at any time.

For more information, visit [australiancancertrials.gov.au](http://australiancancertrials.gov.au).

► See our *Understanding Clinical Trials and Research* booklet.

# Treatment

Treatment for myeloma is highly individual and depends on several factors, such as the type and stage of myeloma, your symptoms and your general health. As myeloma is not curable, the aim is to get the myeloma under control and maintain control for as long as possible.

## Treatment options

**Active monitoring** – People who have been diagnosed with either monoclonal gammopathy of undetermined significance (MGUS) or smouldering myeloma (see page 20) usually do not need treatment straightaway. Most people with MGUS never develop active myeloma. In most cases of smouldering myeloma, having treatment straightaway does not offer any benefits, but a small number of people with high-risk smouldering myeloma may benefit from early therapy.

If tests show you have MGUS or smouldering myeloma, you will need check-ups every 3–12 months. This is called active monitoring. Your doctor will start treatment if you develop symptoms or other significant signs of myeloma.

**Treatment to control active or symptomatic myeloma** – This is often called induction or first-line treatment. It includes a combination of different drugs (see pages 26–30). A stem cell transplant may be suggested for some people (see pages 31–34). Active treatment may be followed by periods of stable disease (plateau phase or remission) when no maintenance therapy or treatment is needed.

**Treatment for symptoms and side effects of myeloma** – These treatments help manage issues associated with myeloma, such as bone

disease, pain, kidney damage, hypercalcaemia, frequent infections and fatigue (see pages 34–37 and 39–47).

**Treatment to prevent the disease returning** – This is called maintenance or consolidation therapy and involves a longer, lower-dose course of an immunomodulator such as lenalidomide, steroids and/or other drugs. It is often used after a stem cell transplant and sometimes after other first-line treatment (see pages 28–30).

**Treatment when the disease comes back** – You may be offered a different type of chemotherapy, a stem cell transplant, steroids or other drugs to regain control of the disease.

### Combining drug therapies

Most people with myeloma will be treated with a combination of two, three or more different drugs.

The combinations may include traditional chemotherapy drugs and steroids, as well as some newer therapies that are known as immunomodulators (see page 28), proteasome inhibitors (see page 29) or monoclonal antibodies (see page 29).

Combinations of drugs are used because each type of drug works differently to kill myeloma cells,

and the combined effect helps treat as much of the disease as possible.

The choice of a particular combination will depend on the type of myeloma, your age and your kidney function. Your haematologist will select the most suitable combination and discuss this with you.

To learn more about the different drug combinations for myeloma, visit [myeloma.org.au](http://myeloma.org.au) or [eviq.org.au](http://eviq.org.au).

## Chemotherapy

Chemotherapy is the treatment of cancer with anti-cancer drugs called cytotoxics. The aim of chemotherapy is to kill cancer cells while doing the least possible damage to healthy cells.

The most commonly used chemotherapy drugs for myeloma include melphalan and cyclophosphamide.

**How it is given** – Some people can have all their chemotherapy as tablets. Others have the drugs injected into a vein (intravenously) or under the skin (subcutaneously). You may need to stay in hospital for some treatments, but this stay is usually short. Your doctor will tell you about the drugs you are having and how long treatment will last. You may have chemotherapy in combination with other treatments, such as one of the immunomodulator drugs or proteasome inhibitors used for myeloma (see pages 28–29).

**Side effects** – Some chemotherapy drugs can cause side effects, such as feeling sick (nausea), fatigue, loss of hair from the body and head, a drop in blood count, mouth sores, diarrhoea and a weakened immune system.

These side effects are temporary and there are ways to prevent or reduce them. Tell your doctor or nurse about any side effects that you experience. Your doctor may prescribe medicine, consider a break in your treatment, or change the treatment you are having. For more information, see the *Managing symptoms and side effects* chapter on pages 39–47.

➤ See our *Understanding Chemotherapy* booklet.

## Immunomodulators

Immunomodulator drugs work by blocking the growth signal for cancer cells and by stimulating the body's immune system to attack the cancer cells. The most common immunomodulators used for myeloma are thalidomide, lenalidomide and pomalidomide.

Thalidomide is an old drug that has new uses. It was given to pregnant women in the 1950s as an anti-nausea drug but was banned because it caused severe birth defects. We now know that thalidomide has anti-cancer properties that can be effective for myeloma. Lenalidomide and pomalidomide are newer types of immunomodulators.

**How they are given** – Immunomodulators are most often given in combination with a steroid and a chemotherapy drug. They are taken as tablets, usually every day or for a certain number of days each month. As some immunomodulator drugs increase the risk of blood clots, some people also take a blood thinner.

**Side effects** – Possible side effects of immunomodulators include drowsiness, constipation, nausea, diarrhoea, rashes, blood clots, low blood count and a weakened immune system. Thalidomide may cause pain, numbness, tingling and muscle weakness in the hands and feet. This is known as peripheral neuropathy (see page 46), but it is not a typical side effect of lenalidomide or pomalidomide.

Females taking immunomodulators should not become pregnant as the fetus would develop serious abnormalities. Sperm is also affected. Males should not conceive and should not donate sperm. If you want to have children, discuss this with your doctor before treatment starts.

## Proteasome inhibitors

Proteasome inhibitors block the breakdown of protein within myeloma cells, causing them to stop growing and die. Commonly used proteasome inhibitors for myeloma are bortezomib and carfilzomib. Some newer drugs such as ixazomib and oprozomib are being studied.

**How they are given** – Bortezomib is given as an injection under the skin or into a vein. It is often used together with steroids and chemotherapy. Carfilzomib is given intravenously.

**Side effects** – Bortezomib and carfilzomib may cause fatigue, diarrhoea, nausea, constipation, low blood counts, infections and shingles. Peripheral neuropathy (see page 46) is common with bortezomib but rare with carfilzomib. Carfilzomib may also cause hypertension, heart problems or worsen pre-existing heart conditions.

## Monoclonal antibodies

Monoclonal antibodies are made in a laboratory but behave like natural antibodies that fight infection and disease. They target cancer cells and interfere with how they grow and survive. Available drugs include daratumumab and elotuzumab.

**How they are given** – Monoclonal antibodies are either injected into a vein (intravenously) or injected under the skin (subcutaneously).

**Side effects** – As these drugs are often given as an injection, they may cause an allergic reaction. Other side effects may be a fever, nausea, diarrhoea and low blood pressure.

## Steroids

Steroids (also known as corticosteroids) are hormones made naturally in the body. They can also be made artificially and used as drugs. These drugs modify the immune system's responses, relieve swelling and inflammation, and actively kill myeloma cells.

**How they are given** – The typical steroids used for myeloma are dexamethasone and prednisolone. These are usually given with chemotherapy or other anti-myeloma drugs. Steroids are most often taken as tablets but can also be given intravenously. They are usually given in high doses, but for short periods only.

**Side effects** – Common side effects include difficulty sleeping, mood changes, increased appetite, fluid retention, heartburn, infections and weight gain. To reduce the risk of sleeplessness at night and irritation to your stomach, take steroids in the morning with food or milk.

Some steroids can affect blood sugar levels. If used for a long period, steroids may cause diabetes. If you have diabetes, you need to monitor your blood sugars often. Always consult your doctor if you want to reduce the dose as stopping steroids suddenly can cause problems.

Several new drug therapies for myeloma are being developed. The cost of these drugs is not subsidised for myeloma on the Pharmaceutical Benefits Scheme (PBS), so they are expensive. If your doctor thinks they are the most promising treatment for you, ask whether there are any clinical trials or compassionate access schemes that may be able to help with the costs.

## Stem cell transplant

You may be offered a stem cell transplant where diseased blood cells are destroyed by high-dose chemotherapy and then replaced with blood stem cells. This is also known as high-dose therapy and stem cell rescue. It aims to destroy as much as possible any remaining myeloma cells and increase the length of the plateau phase (remission). Your own stem cells are most frequently used for this procedure. This is called an autologous transplant. Occasionally, stem cells from a donor may be recommended. This is called an allogeneic transplant.

An autologous transplant is done in several stages. Before the process begins, you have induction treatment to put the myeloma into a plateau phase. Once this is achieved, the stem cells are removed and frozen. You then have high-dose chemotherapy followed by the return of your stem cells. See the next two pages for a detailed description of this process.

Although a stem cell transplant can help some people, it is not suitable for everyone. The high-dose chemotherapy that is given before the transplant can have a lot of side effects.

To work out whether a stem cell transplant is suitable for you, your haematologist will consider your general health, age, the type of myeloma you have, how fast it is growing and how it responds to treatment. The haematologist will discuss the risks and benefits of a stem cell transplant with you. Stem cell transplants are available only at some hospitals, so you may need to be referred to another hospital.

The entire procedure, including recovery, can take months and even up to a year.

## Stem cell transplant steps

A general autologous transplant process is described here, but the process varies from person to person. Detailed information is available from [leukaemia.org.au](http://leukaemia.org.au).

### 1 Collecting stem cells

- The first step is to collect a supply of stem cells.
- This process is called mobilisation and may start with a dose of chemotherapy followed by a special growth factor drug called granulocyte-colony stimulating factor (G-CSF). Or you might simply have a course of G-CSF without the chemotherapy.
- The growth factor drug is given for 5–10 days and will help increase the number of stem cells in the bone marrow, which then enter the bloodstream. This process will take several days.
- The level of stem cells in the blood will be measured and when adequate numbers are present, they are collected via a process called apheresis.

### 2 Separating and storing stem cells

- Apheresis usually involves inserting a needle called a cannula into a vein in each arm. (People with weak veins may need a special line known as an apheresis catheter.)
- Blood is taken from your body through one of the cannulas and passed through a machine called a cell separator. The stem cells are removed, and the rest of the blood is returned to your body through the other cannula.
- This process takes 3–4 hours and may need to be repeated the next day.
- The stem cells are processed and frozen using liquid nitrogen (cryopreserved).
- After the stem cells are collected and stored, you will then have a rest period at home for about a month until the next stage of treatment.

**3****Receiving high-dose chemotherapy**

- High-dose chemotherapy, often referred to as conditioning therapy, is given through a vein. A long, flexible plastic tube is usually used. This may be a peripherally inserted central catheter (PICC line), a Hickman line or a central line.
- About 24 hours before the transplant, you'll have high-dose chemotherapy to kill as many of the myeloma cells as possible. This will also destroy the normal stem cells in the bone marrow. Before and after the chemotherapy is given, you will have fluids through a drip to prevent dehydration and kidney damage.
- Common side effects from the high-dose chemotherapy include infection, nausea, diarrhoea and mouth sores. Because your stem cells have been destroyed, your blood count will be low and you will be more at risk of infections (see pages 43–44).

**4****Transplanting stem cells and engraftment**

- A day or so after the high-dose chemotherapy, your frozen stem cells are thawed and returned to you via a cannula, PICC line, Hickman line or central line. This process takes about an hour, and you may have side effects, such as nausea and stomach cramps. These can be managed with medicines.
- Your stem cells will develop into new blood cells, allowing your bone marrow to recover. This is called engraftment and takes about 10–14 days.
- You will usually stay in hospital for 1–4 weeks, depending on how soon you are well enough to go home.

Some people continue to have drug therapies after a stem cell transplant. This is known as maintenance treatment (see page 26). It is used to keep myeloma responding to treatment for longer.

## Side effects of a stem cell transplant

Recovery time after a stem cell transplant varies depending on your situation. After the transplant, your blood count will be low. You may be more at risk of infections and need transfusions of blood products and intravenous antibiotics. You will be able to go home when your blood count has risen and your general health has improved. You will have regular follow-up care to check your blood counts and progress.

Infection, fatigue and diarrhoea are common side effects during engraftment. The diarrhoea usually stops by the time you go home, but the fatigue can last for months or even up to a year.

## Supportive treatment

You may have some treatments that do not target the myeloma itself, but help to treat symptoms caused by the myeloma. Antibiotics and antiviral drugs may be given to prevent infections, and blood-thinning tablets or injections may be used to prevent blood clots. Other supportive treatments may include bisphosphonates for bone protection, radiation therapy for bone pain and damage, and plasma exchange for dangerous levels of paraprotein in the blood.

### Bisphosphonates

Bisphosphonates are a group of drugs that help strengthen bone and reduce bone pain by preventing further bone weakness or damage caused by myeloma cells. They also control high calcium levels in the blood (see pages 41–42). You will need regular blood tests to monitor your calcium levels and kidney function before and while you are taking bisphosphonates.

**How they are given** – Several types of bisphosphonates are used for myeloma. Most commonly it is given by an injection into the vein. Less commonly, a bisphosphonate can be given by tablet.

**Side effects** – Bisphosphonates can cause stomach upset. You may feel sick and/or have constipation or diarrhoea for a few days.

An uncommon but severe side effect associated with long-term bisphosphonate use is osteonecrosis of the jaw or ONJ. This causes bone tissue in the jaw to breakdown, leading to pain and infection. It is important to visit your dentist for a check-up and have any invasive dental work done before you start treatment. Keep up good dental hygiene by brushing and flossing twice daily, and see the dentist for yearly check-ups. If you need dental work during treatment, let your dentist know that you are taking bisphosphonates and ask your haematologist whether it's possible to have a break in treatment. If you have a tooth removed, you'll have a break from bisphosphonates for 1–3 months until your gum is healed. This is to prevent ONJ.

## **Radiation therapy**

Not all people with myeloma will need radiation therapy. It is used to relieve symptoms, such as bone pain, or to prevent bones from breaking, by reducing the number of myeloma cells in the bones.

Radiation therapy, also known as radiotherapy, uses a controlled dose of radiation to kill or injure cancer cells. The radiation is usually in the form of focused x-ray beams. Treatment is carefully planned to destroy the cancer cells while causing as little harm as possible to your normal tissue.

**How it is given** – You lie under a machine that delivers the radiation to areas with myeloma cells. Each treatment takes only a few minutes, but the first appointment can take 1–3 hours. Radiation therapy may be given as a single dose, or as multiple doses over several days or weeks. You will visit the radiation therapy centre for each of your radiation treatments, rather than staying overnight.

**Side effects** – Radiation therapy can cause both immediate and delayed side effects. The most common side effect is tiredness. Other side effects will depend on the part of the body being treated. Most of these side effects go away within days to weeks of treatment finishing. Tell your radiation oncology team about any side effects you may have.

➤ See our *Understanding Radiation Therapy* booklet.

## **Immunoglobulin replacement therapy**

The majority of people with myeloma have low levels of normal antibodies, which means they are more likely to get infections. You may have a process called immunoglobulin replacement therapy (IRT) to boost your antibody levels and protect you against infections. Whether you need this therapy will depend on if you have had repeated infections and also on the level of any remaining normal antibodies in your blood.

**How it is given** – Immunoglobulin is produced from blood donor plasma and can be injected into a vein (intravenously) or under the skin (subcutaneously). When delivered intravenously, each treatment takes 2–4 hours and most people receive one dose a month. When delivered subcutaneously, it takes about 30 minutes and is delivered by a pump or a slow injection.

**Side effects** – Side effects are uncommon with IRT. Occasionally, some people experience a headache, low-grade fever, nausea, diarrhoea or an allergic reaction at the site of the injection. Side effects are more common with the first treatment and are temporary.

### **Plasma exchange**

Plasma exchange may be used if the level of paraprotein in the blood is very high, making the blood thicker and slower to circulate (see page 42). This causes symptoms such as blurred vision and confusion.

**How it is given** – A needle is placed into a vein in each arm. Blood is removed from one arm and passed through a machine that separates it into each of the blood components. The plasma, which contains much of the extra paraprotein, is removed and replaced with either plasma from a donor or a plasma substitute such as albumin (a blood protein). The blood is then returned to the body via the other arm. This process usually takes a few hours and is not painful.

## **Palliative treatment**

In some cases of advanced myeloma, the medical team may talk to you about palliative treatment. Palliative treatment helps to improve quality of life by alleviating symptoms of cancer. It can be used at any stage of advanced cancer. As well as slowing the spread of cancer, palliative treatment can relieve pain and help manage other symptoms. Treatment may include blood transfusions, radiation therapy, chemotherapy or other drug therapies. Palliative treatment is one aspect of palliative care, in which a team of health professionals aim to meet your physical, emotional, cultural, social and spiritual needs.

## Key points about treating myeloma

**Main treatments** Treatment for myeloma is highly individual and depends on the type and stage of myeloma.

You may have:

- active monitoring – not everyone diagnosed with myeloma needs treatment straightaway. It is common to wait until the myeloma is causing symptoms before starting treatment. In this case, you will have regular appointments to check for symptoms
- first-line treatment to control the myeloma – this is usually a combination of traditional chemotherapy drugs, steroids and another type of drug, such as thalidomide, lenalidomide or bortezomib
- supportive treatment for myeloma symptoms and side effects
- maintenance treatment to prevent myeloma coming back.

### **Other treatments**

While not suitable for everyone, some people will have a stem cell transplant to help destroy remaining myeloma cells and improve the length of the plateau phase (remission).

Palliative treatment can help to ease the symptoms of advanced myeloma.

# Managing symptoms and side effects

Myeloma and its different treatments may cause symptoms and side effects. Most of these issues are caused by the build-up of myeloma cells in the bone marrow and the presence of paraprotein in the blood or urine. This chapter discusses how to manage these symptoms. Your health care team may refer to these as supportive treatments.

## Bone disease

Bone disease is one of the most common side effects experienced by people with myeloma. The myeloma cells release chemicals that damage the cells that normally repair damaged bone. When this happens, bone breaks down faster than it can be repaired, causing bone pain, bone damage (lytic lesions), or even fractures. The middle or lower back, the rib cage and the hips are the most frequently affected areas.

The rapid breakdown of bone can lead to an increase in blood calcium levels (hypercalcaemia). For more information, see pages 41–42.

A group of drugs called bisphosphonates are used to treat bone disease. They help to control hypercalcaemia, manage existing bone disease and slow down any further bone destruction. For more information on bisphosphonates, see pages 34–35.

👏 Increasingly, those of us with myeloma are living longer and with a better quality of life – so much so that research is now needing to be done on longer-term effects of the cancer and its treatments. This is almost a nice ‘problem’ to have! 🗨️ *Brigita*

## Pain

Pain is the most common symptom at diagnosis for people with myeloma. It is often related to bone damage that has been caused by the disease.

Regular reviews by pain management specialists or palliative care specialists will help keep your pain under control. It's better to take pain medicine regularly, rather than waiting until you feel pain.

Some people may need further treatment to manage pain. This may include localised radiation therapy or, in some specific cases, vertebroplasty. This involves injecting medical-grade cement into the spine because it has collapsed.

### Tips for managing pain

- Complementary therapies, such as relaxation and meditation, sometimes work well when used along with pain medicine.
- Talk to a psychologist about cognitive behaviour therapy (CBT). This approach aims to change how you feel pain by changing your thoughts.
- Listen to our free relaxation CD and podcast episode "Managing Cancer Pain" and read our booklets *Overcoming Cancer Pain* and *Understanding Complementary Therapies*. You can find the recordings and booklets at [cancercouncil.com.au](http://cancercouncil.com.au).
- Visit Myeloma Australia at [myeloma.org.au/resources](http://myeloma.org.au/resources) to download the *Pain and Myeloma* information sheet.
- Tell your treatment team if you are experiencing pain – don't wait for them to ask.

## Kidney damage

Kidney problems can develop in people with myeloma for various reasons. The paraprotein produced by myeloma cells can damage the kidneys. This is particularly common with the Bence Jones protein (see page 13). Other complications of myeloma, such as dehydration, infection and hypercalcaemia, can also damage the kidneys, as can some of the drugs used to treat myeloma and its symptoms.

People with myeloma should drink three litres of fluids a day. This can include water, tea, coffee, fruit juice and milk. Ask your doctor if it's necessary to avoid using painkillers that contain a non-steroidal anti-inflammatory drug (NSAID), because these can also damage the kidneys. It is also important to treat any infections quickly (see pages 43–44) to limit further stress on the kidneys. Also ask your doctor if you should avoid contrast dye during CT or MRI scans.

The treatment for kidney damage in people with myeloma will depend on the cause. Often, the damage is temporary and the kidneys can recover. In some people, the kidney problems are permanent and require dialysis. This is a way of filtering the blood using a machine.

## High calcium levels in the blood

The myeloma cells in the bones can sometimes start to break down some of the bone cells, which releases calcium into the blood. This condition is called hypercalcaemia. It can cause symptoms such as tiredness, nausea, constipation, bone pain, thirst, irritability and confusion. In some people, hypercalcaemia is discovered during a blood test before any symptoms develop.

People with hypercalcaemia need to drink extra fluids. However, they might also require treatment in hospital, which may include intravenous fluids, steroids and bisphosphonates. Treatment of the myeloma itself will often help to control the high calcium levels in the blood.

## Thicker blood

Occasionally, the myeloma cells release so much paraprotein into the blood that the blood becomes thick and starts to circulate more slowly. This is known as hyperviscosity syndrome.

The thickened blood may block small blood vessels in the brain, and this can lead to blurred vision, confusion, headaches and dizziness. It can also cause stroke-like symptoms such as slurred speech and weakness on one side of the body. A process called plasma exchange (see page 37) can quickly remove the excess paraprotein from the blood and improve symptoms.

## Anaemia

Anaemia means you have a low red blood cell count. You may look pale, feel weak and tired, and be breathless. It is common to have anaemia when myeloma is diagnosed, but this will normally get better when treatment begins to control the myeloma.

Sometimes anaemia develops because of the treatment itself. If anaemia is causing you significant symptoms, your doctor may suggest a blood transfusion to increase your red blood cell count. The blood will be given to you through a catheter inserted into a vein in your arm.

## Brigita's story

When I was diagnosed with myeloma, my doctor prescribed nine chemotherapy cycles leading up to a stem cell transplant a year later. I've also had thalidomide and steroid treatment.

After I had the transplant, I was feeling good, but looking back at photos, I think it affected me more than I realised at the time.

Luckily, all the treatment hasn't damaged my kidneys, but I have

had other side effects. At times, I've been so fatigued that my brain can't seem to think, but I just wait until I feel less doopey. I also became very susceptible to infections. A small scrape can quickly become serious.

I'm still figuring it out. Some things are caused by ageing, others by the cancer and the drugs. But when I feel like an infection is coming on, I've learnt to see my doctor straightaway.

## Infections

Many of the active drug therapies, such as high-dose steroids and treatments such as pomalidomide, lenalidomide, bortezomib, carfilzomib and chemotherapy, can also weaken your immune system. This makes you more likely to get infections and less able to fight any infections that do occur. See the next page for ways to reduce your risk of infection and when you need to contact your doctor urgently.

If your white blood cell count falls very low, it's important to treat infections with appropriate antibiotics immediately. You may also be given a course of the special growth factor drug G-CSF and if you have repeated infections, you may be given intravenous immunoglobulins (antibodies).

## Taking care with infections

### Reduce your risk

To prevent the spread of infection:

- check with your doctor about having the flu and pneumococcal vaccines
- ask people close to you to consider having a flu shot
- ask family and friends with a cold, flu or other contagious infection (e.g. chickenpox, measles or a cold sore) to wait until they are well before visiting
- as far as practical, avoid close contact with people you live with if they are unwell
- try to avoid crowded places, such as shopping centres or public transport in peak hour
- wash your hands thoroughly with soap and water before preparing food, eating and after using the toilet
- prepare and store food properly to avoid foodborne illness and food poisoning
- eat freshly cooked foods; avoid raw fish, undercooked meat, raw eggs, seafood and soft cheeses; wash fruits and vegetables well before eating.

### When to seek medical help

Contact your doctor or go to the nearest hospital emergency department immediately if you experience one or more of the following symptoms:

- a temperature of 38°C or higher
- chills or shivering
- sweating, especially at night
- burning or stinging feeling when urinating
- a severe cough or sore throat
- shortness of breath
- vomiting that lasts more than a few hours
- severe abdominal pain, constipation or diarrhoea
- unusual bleeding or bruising, such as nosebleeds, blood in your urine or black bowel motions (poo)
- prolonged faintness or dizziness and a rapid heartbeat
- any sudden deterioration in your health.

## Fatigue

Feeling very tired and lacking the energy to do day-to-day things is known as fatigue. It is different from normal tiredness because it often doesn't go away with rest or sleep.

Fatigue is very common in people with myeloma and may last for weeks or months after treatment ends. It can be caused by the cancer itself, or by the physical and emotional side effects of diagnosis and treatment.

Sometimes people don't tell their doctor about fatigue because they think nothing can be done about it. However, your treatment team may be able to suggest strategies to manage the fatigue.

### Tips for managing fatigue

- Try to keep as active as possible. See Cancer Council's *Exercise for People Living with Cancer* booklet.
- Plan activities for the time of day when you tend to feel most energetic.
- If you're having trouble sleeping, try some relaxation and meditation exercises. Call Cancer Council **13 11 20** for resources that may help.
- Fatigue is a common side effect of cancer treatment, but it can also be a symptom of depression (see page 50).
- Download Myeloma Australia's information sheet on fatigue from [myeloma.org.au/resources](http://myeloma.org.au/resources).
- Listen to our "Managing Cancer Fatigue" podcast episode at [cancercouncil.com.au/podcasts](http://cancercouncil.com.au/podcasts).

## Nerve and muscle effects

Many people with myeloma develop tingling (“pins and needles”), pain or numbness in the fingers and/or toes, and muscle weakness in the legs. This is called peripheral neuropathy because it involves the nerves of the peripheral nervous system.

Peripheral neuropathy may be caused by the myeloma itself. The paraprotein produced by myeloma cells can travel through the bloodstream, build up in nerve tissue, and damage the nerve cells. Some myeloma treatments, such as thalidomide and bortezomib, can also damage the nerve cells. Always tell your doctor if you have tingling or numbness, as your treatment may need to be adjusted.

### Tips for managing peripheral neuropathy

- Take care when moving around as you are more likely to fall if your feet are numb or your legs are weak.
- Keep your hands and feet warm to help the blood circulate. Gloves and warm socks can help when it's cold or soak your hands and feet in warm water.
- Wear properly fitting shoes – tight shoes can make the tingling worse, while loose shoes may make you stumble.
- If your symptoms are severe, talk to your doctor about whether you can take any medicines that offer relief.
- Visit Myeloma Australia at [myeloma.org.au](http://myeloma.org.au) to download the *Managing Peripheral Neuropathy* booklet. Or download our fact sheet *Understanding Peripheral Neuropathy and Cancer* from [cancercouncil.com.au](http://cancercouncil.com.au).

## Key points about symptoms and side effects

### Common symptoms and side effects

- Bone disease – usually treated with drugs called bisphosphonates.
- Pain – often linked to bone damage that has been caused by the disease.
- Kidney problems – the kidneys usually recover, but if the problem is permanent, you may need dialysis.
- Excess calcium in the blood (hypercalcaemia) – breakdown of bone cells can cause symptoms such as tiredness, nausea, constipation, bone pain and confusion.
- Thicker blood – caused by paraprotein being released into the blood.
- Anaemia – the myeloma itself and chemotherapy treatment can both lead to low levels of red blood cells (anaemia).
- Frequent infections – contact your doctor or hospital immediately if you develop a temperature of 38°C or higher, or other signs of infection.
- Extreme tiredness and lack of energy (fatigue) – a common side effect that may last for weeks or months.
- Peripheral neuropathy – with tingling, pain, and numbness of fingers and toes and muscle weakness in the legs.

### Managing symptoms and side effects

Talk to your treatment team about any symptoms or side effects that you have. They may be able to suggest strategies or adjust your treatment.

# Looking after yourself

Cancer can cause physical and emotional strain, so it's important to look after your wellbeing. Cancer Council has free booklets and programs to help you during and after treatment. Call 13 11 20 to find out more, or visit [cancercouncil.com.au](http://cancercouncil.com.au).

**Eating well** – Healthy food can help you cope with treatment and side effects. A dietitian can explain how to manage any special dietary needs or eating problems and choose the best foods for your situation.

➤ See our *Nutrition and Cancer* booklet.

**Staying active** – Physical activity can reduce tiredness, improve circulation and lift mood. The right exercise for you depends on what you are used to, how you feel and your doctor's advice.

➤ See our *Exercise for People Living with Cancer* booklet.

**Complementary therapies** – Complementary therapies are designed to be used alongside conventional medical treatments. Therapies such as massage, relaxation and acupuncture can increase your sense of control, decrease stress and anxiety, and improve your mood. Let your doctor know about any therapies you are using or thinking about trying, as some may not be safe or evidence based.

➤ See our *Understanding Complementary Therapies* booklet.

Alternative therapies are therapies used instead of conventional medical treatments. These are unlikely to be scientifically tested and may prevent successful treatment of the cancer. Cancer Council does not recommend the use of alternative therapies as a cancer treatment.

**Work and money** – Cancer can change your financial situation, especially if you have extra medical expenses or need to stop working. Getting professional financial advice and talking to your employer can give you peace of mind. You can also check with a social worker or Cancer Council whether any financial assistance is available to you.

➤ See our *Cancer and Your Finances* and *Cancer, Work & You* booklets.

**Relationships** – Having cancer can affect your relationships with family, friends and colleagues in different ways. Cancer is stressful, tiring and upsetting, and this may strain relationships. It may also result in positive changes to your values, priorities or outlook on life. Give yourself time to adjust to what's happening, and do the same for those around you. It may help to discuss your feelings with each other.

➤ See our *Emotions and Cancer* booklet.

**Sexuality** – Cancer can affect your sexuality in physical and emotional ways. The impact of these changes depends on many factors, such as treatment and side effects, your self-confidence, and if you have a partner. Although sexual intercourse may not always be possible, closeness and sharing can still be part of your relationship.

➤ See our *Sexuality, Intimacy and Cancer* booklet.

**Contraception and fertility** – If you can have sex, you may need to use certain types of contraception to protect your partner or avoid pregnancy for a time. Your doctor will explain what precautions to take. They will also tell you if treatment will affect your fertility permanently or temporarily. If having children is important to you, discuss the options with your doctor before starting treatment.

➤ See our *Fertility and Cancer* booklet.

# Life after treatment

For most people, the cancer experience doesn't end on the last day of treatment. Life after cancer treatment can present its own challenges. You may have mixed feelings when treatment ends, and worry that every ache and pain means the cancer is coming back.

Some people say that they feel pressure to return to “normal life”. It is important to allow yourself time to adjust to the physical and emotional changes, and establish a new daily routine at your own pace. Your family and friends may also need time to adjust.

Cancer Council 13 11 20 can help you connect with other people who have had cancer, and provide you with information about the emotional and practical aspects of living well after cancer.

➤ See our *Living Well After Cancer* booklet.

## Dealing with feelings of sadness

If you have continued feelings of sadness, have trouble getting up in the morning or have lost motivation to do things that previously gave you pleasure, you may be experiencing depression.

This is quite common among people who have had cancer.

Talk to your GP, as counselling or medication – even for a short time – may help. Some people

can get a Medicare rebate for sessions with a psychologist. Ask your doctor if you are eligible. Cancer Council may also run a counselling program in your area.

For information about coping with depression and anxiety, call Beyond Blue on **1300 22 4636** or visit [beyondblue.org.au](http://beyondblue.org.au). For 24-hour crisis support, call Lifeline **13 11 14** or visit [lifeline.org.au](http://lifeline.org.au).

## Follow-up appointments

Whether or not you have treatment for myeloma, you will need regular check-ups to keep an eye on your health. Your doctor will decide how often you need check-ups because everyone is different. Check-ups will become less frequent if your condition has stabilised or you have no further problems.

Blood tests, urine tests, and bone marrow biopsies may be used to check your health. Occasionally x-rays and scans may also be used. Your doctor may note the levels of antibodies and proteins in the blood and urine.

If you notice any symptoms between appointments, tell your doctor as soon as possible. You don't have to wait until the next scheduled appointment.

🗨️ I've had many appointments with my doctors, mostly to manage pain caused by the myeloma. My doctors also monitor my bone lesions. 🗨️ *Sam*

## When myeloma returns

When myeloma returns, it is called disease progression, relapse or recurrence. You and your doctor will need to discuss what treatment is needed to try to regain control of the disease.

While options for managing disease progression may have been considered in the initial treatment plan, many doctors like to discuss

all the options again. This is because the risks and benefits of treatment are not as clear in people whose myeloma has relapsed, and your views and the disease characteristics may have changed.

In some people, the original treatment can be repeated successfully, especially if the response to the treatment was good. In other people, the myeloma may not respond to the treatment that was used previously. This is called resistant or refractory disease.

Treatment options for resistant disease may include:

- taking a different combination of drugs (see pages 26–30)
- treatment with a different class of drugs (see pages 26–30)
- having another stem cell transplant (see pages 31–34)
- participating in a clinical trial to access new drugs being developed and tested (see page 24).

New treatments are being developed all the time, so if the myeloma comes back, talk to your doctor about what treatment options are available.

## Seeking support

A cancer diagnosis can affect every aspect of your life. You will probably experience a range of emotions – fear, sadness, anxiety, anger and frustration are all common reactions. Cancer also often creates practical and financial issues.

There are many sources of support and information to help you, your family and carers navigate all stages of the cancer experience, including:

- information about cancer and its treatment
- access to benefits and programs to ease the financial impact of cancer treatment
- home care services, such as Meals on Wheels, visiting nurses and home help
- aids and appliances
- support groups and programs
- counselling services.

The availability of services may vary depending on where you live, and some services will be free, but others might have a cost.

To find good sources of support and information, you can talk to the social worker or nurse at your hospital or treatment centre, or get in touch with Cancer Council 13 11 20.

“ My family members don't really understand what it's like to have cancer thrown at you, but in my support group, I don't feel like I have to explain. ” Sam

## Support from Cancer Council

Cancer Council offers a range of services to support people affected by cancer, their families and friends. Services may vary depending on where you live.

### Cancer Council 13 11 20

Trained professionals will answer any questions you have about your situation and link you to services in your area (see inside back cover).

### Information resources

Cancer Council produces booklets and fact sheets on over 25 types of cancer, as well as treatments, emotional and practical issues, and recovery. Call **13 11 20** or visit [cancercouncil.com.au](http://cancercouncil.com.au).

### Practical help

Cancer Council can help you find services or offer guidance to manage the practical impact of a cancer diagnosis. This may include access to transport and accommodation services.

### Legal and financial support

If you need advice on legal or financial issues, we can refer you to qualified professionals. These services are free for people who can't afford to pay. Financial assistance may also be available. Call Cancer Council **13 11 20** to ask if you are eligible.

### Peer support services

You might find it helpful to share your thoughts and experiences with other people affected by cancer. Cancer Council can link you with individuals or support groups by phone, in person, or online. Call **13 11 20** or visit [cancercouncil.com.au/OC](http://cancercouncil.com.au/OC).

## Support from Myeloma Australia

Myeloma Australia is a national not-for-profit organisation dedicated to providing information and support for people affected by myeloma. It aims to:

- raise awareness of the disease in the community
- promote research
- advocate to governments for more generous support for the myeloma community
- support patients, carers and health care professionals through its specialist myeloma support nurses.

**Myeloma support nurses** – If you would like to talk to someone about any aspect of myeloma, its treatment and management, call Myeloma Australia's toll-free Telephone Support Line on 1800 MYELOMA (1800 693 566). The service is available during business hours Monday to Friday, and a myeloma support nurse will answer your call in confidence.

**Support groups** – Find details of myeloma-specific support groups by searching Myeloma Australia's website at [myeloma.org.au](http://myeloma.org.au) or calling a support nurse on 1800 693 566. In NSW, a telephone support group is available through Cancer Council for those unable to attend a group in person. To find out more, visit [cancercouncil.com.au](http://cancercouncil.com.au).

**Information resources** – Download a comprehensive range of information resources, including booklets and fact sheets on many aspects of myeloma, its treatments and supportive care issues, from [myeloma.org.au/resources](http://myeloma.org.au/resources).

## Useful websites

You can find many useful resources online, but not all websites are reliable. These websites are good sources of support and information.

# Caring for someone with cancer

You may be reading this booklet because you are caring for someone with cancer. What this means for you will vary depending on the situation. Being a carer can bring a sense of satisfaction, but it can also be challenging and stressful.

It is important to look after your own physical and emotional wellbeing. Give yourself some time out and share your concerns with somebody neutral such as a counsellor or your doctor, or try calling Cancer Council 13 11 20. There is a wide range of support available to help you with both the practical and emotional aspects of your caring role.

**Support services** – Support services such as Meals on Wheels, home help or visiting nurses can help you in your caring role. You can find local services, as well as information and resources, through the Carer Gateway. Call 1800 422 737 or visit [carergateway.gov.au](http://carergateway.gov.au).

**Support groups and programs** – Many cancer support groups and cancer education programs are open to carers as well as to people with cancer. Support groups and programs offer the chance to share experiences and ways of coping.

**Carers Association** – Carers NSW, a statewide organisation specifically for carers, can provide information and support. Call 02 9280 4744 or visit [carersnsw.org.au](http://carersnsw.org.au).

**Cancer Council** – You can call Cancer Council 13 11 20 or visit [cancercouncil.com.au](http://cancercouncil.com.au) to find out more about carers' services.

➤ See our *Caring for Someone with Cancer* booklet.

# Question checklist

Asking your doctor questions will help you make an informed choice. You may want to include some of the questions below in your own list.

## Diagnosis

- What type of myeloma do I have?
- What tests do I need?
- Has the cancer spread? If so, where has it spread? How fast is it growing?
- Are the latest tests and treatments for this cancer available in this hospital?
- Will a multidisciplinary team be involved in my care?
- Are there clinical guidelines for this type of cancer?

## Treatment

- What treatment do you recommend? What is the aim of the treatment?
- Are there other treatment choices for me? If not, why not?
- If I don't have the treatment, what should I expect?
- How long do I have to make a decision?
- I'm thinking of getting a second opinion. Can you recommend anyone?
- How long will treatment take? Will I have to stay in hospital?
- Are there any out-of-pocket expenses not covered by Medicare or my private health cover? Can the cost be reduced if I can't afford it?
- How will we know if the treatment is working?
- Are there any clinical trials or research studies I could join?

## Side effects

- What are the risks and possible side effects of each treatment?
- Will I have a lot of pain? What will be done about this?
- Can I work, drive and do my normal activities while having treatment?
- Will the treatment affect my sex life and fertility?
- Should I change my diet or physical activity during or after treatment?

## After treatment

- How often will I need check-ups after treatment?
- When the myeloma returns, how will I know? What treatments could I have?

# Glossary

## **active monitoring**

Regular check-ups to test for signs or symptoms of a disease. Used for monoclonal gammopathy of undetermined significance (MGUS) and smouldering myeloma.

## **active myeloma**

Myeloma that requires treatment because it is causing symptoms or test results indicate a high risk of the disease progressing. Also known as symptomatic myeloma.

## **albumin**

The main protein found in the blood. The protein level provides some indication of overall health and nutritional status.

## **allogeneic stem cell transplant**

A transplant where the stem cells are taken from one person and given to another.

## **anaemia**

A reduction in the number or quality of red blood cells in the body.

## **anaesthetic**

A drug that stops a person feeling pain during a medical procedure. Local and regional anaesthetics numb part of the body; a general anaesthetic causes a temporary loss of consciousness.

## **antibody**

Part of the body's immune system. Antibodies are proteins made by plasma cells in response to an invader (antigen) in the body. They help protect against viruses, bacteria and other foreign substances. Antibodies are also known as immunoglobulins. Myeloma cells make an abnormal antibody called paraprotein.

## **antigen**

Any substance that causes the immune system to respond, often prompting plasma cells to make antibodies.

## **apheresis**

A procedure where blood is removed from the body and passed through a machine to separate a component such as stem cells. The remainder of the blood is then returned to the body. It is a key step in a stem cell transplant.

## **asymptomatic myeloma**

See smouldering myeloma.

## **autologous stem cell transplant**

A process that involves taking stem cells or bone marrow from a person's own body and then giving them back following high-dose chemotherapy.

## **Bence Jones protein**

The name of a light chain protein found in the urine of some people with myeloma. For these people, urine tests can be used to help diagnose and monitor the disease.

## **benign**

Not cancerous or malignant.

## **beta-2 microglobulin (B2M)**

A protein found in the blood. High levels occur in people with active myeloma.

## **biopsy**

The removal of a sample of tissue from the body for examination under a microscope to help diagnose a disease.

## **bisphosphonate**

A type of drug that protects against bone breakdown.

**blood**

A watery body fluid that flows through the circulatory system. Blood comprises plasma, red blood cells, white blood cells and platelets.

**blood count**

A test that counts the number of red blood cells, white blood cells and platelets in the blood.

**bone marrow**

The soft, spongy material inside bones. Bone marrow produces stem cells that become red blood cells, white blood cells and platelets.

**bone marrow aspiration**

The removal of a small amount of bone marrow liquid (aspirate) with a needle for examination under a microscope.

**calcium**

A mineral found mainly in the hard part of bones, where it is stored.

**cannula**

A plastic tube inserted into a narrow opening (usually a vein) so that fluids can be introduced or removed.

**central line**

A type of central venous access device used to give direct access to a vein in the chest or neck.

**chemotherapy**

A cancer treatment that uses drugs to kill cancer cells or slow their growth.

**chromosome**

A threadlike structure found in all body cells (except red blood cells).

**clinical trial**

A study that tests new approaches to prevention, screening or treatment.

**corticosteroids**

See steroids.

**CRAB criteria**

A set of myeloma-defining events used to help identify people who need treatment.

The letters stand for the events:

C=calcium elevation; R=renal damage; A=anaemia; B=bone abnormalities. Often combined with the SLiM criteria to form the SLiM-CRAB criteria.

**CT scan**

Computerised tomography scan. This scan uses x-rays to create a detailed, cross-sectional picture of the body.

**cytogenetic test**

A test that checks whether cells have an abnormality in their chromosomes.

**disease progression**

When tests show myeloma is increasing and needs treatment. Also known as relapse or recurrence.

**engraftment**

The process by which transplanted stem cells develop into new blood cells.

**fluorescence in situ hybridisation (FISH)**

A test used to look for abnormal chromosomes in myeloma cells.

**free light chains**

See light chains.

**granulocyte-colony stimulating factor (G-CSF)**

A growth factor drug used to help the body make more stem cells so they can be collected for a transplant, or to

increase the number of white blood cells if they are low.

#### **growth factor**

A protein that stimulates the development and growth of cells.

#### **haematologist**

A doctor who specialises in studying and treating diseases of the blood, bone marrow and lymphatic system.

#### **heavy chains**

Long chains of proteins in an antibody such as paraprotein.

#### **Hickman line**

A type of central venous access device inserted into a vein in the chest.

#### **high-risk myeloma**

See active myeloma.

#### **hypercalcaemia**

Higher than normal level of calcium in the blood.

#### **hyperviscosity**

A syndrome triggered when blood thickens and starts to circulate more slowly. May occur if myeloma cells release large amounts of paraprotein into the blood.

#### **immunoglobulin**

See antibody.

#### **immunoglobulin replacement therapy (IRT)**

Often given to people who have repeated infections.

#### **immunomodulators**

Drugs that interact with the immune system to attack cancer cells in a number of different ways. Thalidomide, lenalidomide and pomalidomide are

immunomodulator drugs that are used to treat myeloma.

#### **light chains**

Short chains of proteins in an antibody such as paraprotein. Often referred to as Bence Jones protein when found in the urine of people with myeloma, or as free light chains when found in their blood.

#### **lymphocyte**

A type of white blood cell that helps fight infection. Lymphocytes destroy bacteria, viruses and other harmful substances.

#### **lytic lesions**

Areas where bone has been damaged.

#### **malignant**

Cancer. Malignant cells can spread (metastasise) and eventually cause death if they cannot be treated.

#### **medical oncologist**

A doctor who specialises in treating cancer with drug therapies.

#### **monoclonal antibodies**

A group of targeted therapy drugs that lock onto a specific protein on the surface of cancer cells and interfere with the cells' growth or survival.

#### **monoclonal gammopathy of undetermined significance (MGUS)**

A non-cancerous condition in which low levels of paraprotein are present in the blood. This condition may increase the risk of developing myeloma.

#### **M-protein**

See paraprotein.

#### **myeloma**

Cancer of the plasma cells. Also called multiple myeloma.

### **osteonecrosis of the jaw (ONJ)**

A condition in which bone tissue of the jaw breaks down, causing pain.

### **osteoporosis**

Thinning and weakening of the bones that can lead to bone pain and fractures.

### **palliative treatment**

Medical treatment for people with advanced cancer to help them manage pain and other physical and emotional symptoms of cancer. Treatment may include blood transfusions, radiation therapy, chemotherapy or other drug therapies.

### **paraprotein**

A substance produced when plasma cells multiply abnormally. Also called M-protein or monoclonal protein.

### **pathologist**

A specialist doctor who interprets the results of blood tests and biopsies.

### **peripheral neuropathy**

Damage to the nerves that are located away from the brain and spinal cord. This causes weakness, numbness, tingling or pain, usually in the hands and feet.

### **peripherally inserted central catheter (PICC) line**

A type of central venous access device that is inserted into a vein in the arm.

### **plasma**

The clear fluid part of the blood that carries red blood cells, white blood cells and platelets.

### **plasma cells**

A type of white blood cell that stays mostly in the bone marrow. Plasma cells make antibodies.

### **plasma exchange**

When the plasma portion of the blood is removed and replaced with donated plasma or a plasma substitute.

### **plateau phase**

A period of time when myeloma is stable. Also called remission.

### **platelets**

One of the three main types of cells found in the blood. They help the blood to clot and stop bleeding.

### **prognosis**

The expected outcome of a person's disease.

### **proteasome inhibitors**

Drugs that block the breakdown of protein within myeloma cells, causing them to stop growing and die.

### **radiation oncologist**

A doctor who specialises in treating cancer with radiation therapy.

### **radiation therapy**

The use of targeted radiation to kill or damage cancer cells so they cannot grow, multiply and spread. The radiation is usually in the form of x-ray beams. Also called radiotherapy.

### **red blood cells**

One of the three main types of cells found in the blood. They carry oxygen around the body.

### **refractory disease**

Disease that does not respond to treatment. Also called resistant disease.

### **relapse**

See disease progression.

### **remission**

See plateau phase.

### **serum free light chain assay**

A test that can detect free light chains in the blood. These can be a sign of myeloma.

### **SLiM criteria**

A set of signs of myeloma used to help identify people who need treatment. The letters stand for the biomarkers: S=significant plasmacytosis (myeloma cells in bone marrow); Li=light chain ratio; M=MRI lesions (bone abnormalities found by MRI). Often combined with the CRAB criteria to form the SLiM–CRAB criteria.

### **smouldering myeloma**

Early myeloma that does not cause the person any problems and does not need treatment. May progress to active myeloma so needs active monitoring.

Also known as asymptomatic myeloma.

### **solitary plasmacytoma**

A single tumour formed in the bone or tissue by cancerous plasma cells.

### **staging**

The use of various tests to work out how far the disease has progressed.

### **stem cells**

Unspecialised cells from which mature cells develop. Stem cells are found in the bone marrow.

### **stem cell transplant**

A treatment in which diseased blood cells are destroyed by high-dose chemotherapy, then replaced by healthy stem cells. An autologous transplant involves using the person's own stem cells. An allogeneic transplant uses stem cells from another person.

### **steroids (or corticosteroids)**

A group of drugs that are mostly used to reduce inflammation.

### **symptomatic myeloma**

See active myeloma.

### **trephine biopsy**

The removal of a bone tissue sample using a needle.

### **white blood cells**

One of the three main types of cells found in the blood. They help fight infection.

## How you can help

At Cancer Council, we're dedicated to improving cancer control. As well as funding millions of dollars in cancer research every year, we advocate for the highest quality care for cancer patients and their families. We create cancer-smart communities by educating people about cancer, its prevention and early detection. We offer a range of practical and support services for people and families affected by cancer. All these programs would not be possible without community support, great and small.

**Join a Cancer Council event:** Join one of our community fundraising events such as Daffodil Day, Australia's Biggest Morning Tea, Relay For Life, Girls' Night In and other Pink events, or hold your own fundraiser or become a volunteer.

**Make a donation:** Any gift, large or small, makes a meaningful contribution to our work in supporting people with cancer and their families now and in the future.

**Buy Cancer Council sun protection products:** Every purchase helps you prevent cancer and contribute financially to our goals.

**Help us speak out for a cancer-smart community:** We are a leading advocate for cancer prevention and improved patient services. You can help us speak out on important cancer issues and help us improve cancer awareness by living and promoting a cancer-smart lifestyle.

**Join a research study:** Cancer Council funds and carries out research investigating the causes, management, outcomes and impacts of different cancers. You may be able to join a study.

To find out more about how you, your family and friends can help, please call your local Cancer Council.

# Cancer Council

## 13 11 20

Being diagnosed with cancer can be overwhelming. At Cancer Council, we understand it isn't just about the treatment or prognosis. Having cancer affects the way you live, work and think. It can also affect our most important relationships.

When disruption and change happen in our lives, talking to someone who understands can make a big difference. Cancer Council has been providing information and support to people affected by cancer for over 50 years.

Calling 13 11 20 gives you access to trustworthy information that is relevant to you. Our cancer nurses are available to answer your questions and link you to services in your area, such as transport, accommodation and home help. We can also help with other matters, such as legal and financial advice.

If you are finding it hard to navigate through the health care system, or just need someone to listen to your immediate concerns, call 13 11 20 and find out how we can support you, your family and friends.

Cancer Council services and programs vary in each area.  
13 11 20 is charged at a local call rate throughout Australia (except from mobiles).

Interpreter

**If you need information in a language other than English, an interpreting service is available. Call 13 14 50.**

**If you are deaf, or have a hearing or speech impairment, you can contact us through the National Relay Service. [communications.gov.au/accesshub/nrs](https://communications.gov.au/accesshub/nrs)**

**Cancer  
Council**  
**13 11 20**

For information and support on cancer-related issues, call Cancer Council **13 11 20**. This is a confidential service.

For further information and details, visit our website, [cancercouncil.com.au](http://cancercouncil.com.au).

*This booklet is funded through the generosity of the people of NSW.*
